

Job Board / Freelance Marketplace App

Project Type: Full-Stack / MERN

1. Project Overview

Develop a two-sided marketplace where employers publish opportunities and candidates find and apply for them. Ownership and role checks are a central part of the assignment.

2. Objective

The aim is to complete the project as a working, reviewable piece of software or analysis. The implementation should be organized, reproducible and clear enough for another developer to continue from it.

3. Core Requirements

- Support employer and candidate accounts.
- Employers can create, edit, close and manage their own postings.
- Candidates can browse, search and filter open jobs.
- Candidates can submit an application with profile information and a short cover message or portfolio link.
- Employers can view applicants for their own jobs and update application status.
- Candidates can see the status of their applications.
- Prevent unauthorized management actions even if a user manually changes a URL or API request.
- Handle duplicate applications and closed jobs intentionally.

4. Suggested Technology

- MERN or comparable full-stack stack
- Database
- Authentication
- REST API

5. Project Documentation

Documentation is part of the assignment, not an afterthought. Keep it specific to the work actually completed. At minimum, cover the following:

- User roles; schema; job/application lifecycle; authorization rules; search/filter behavior; API summary; setup and demo accounts.

The README should also include installation/setup steps, exact run commands, project structure, screenshots or sample outputs where useful, and any known limitations. Do not report results that were not produced by the submitted project.

6. Code and Project Standards

- Use clear folder and file names. Remove abandoned experiments, duplicate files and generated clutter before submission.
- Do not commit passwords, API keys, tokens or private credentials. Use environment variables and provide an example configuration file when needed.
- Keep dependencies documented and make sure the project can be started using the instructions in the README.
- Use realistic sample data where mock data is required. Do not fill the interface with meaningless placeholder records.
- Check the main workflow from a fresh run before submitting. Broken setup instructions will be treated as an incomplete submission.

7. Final Submission

- **GitHub Repository Link:** Share the link to the final repository. It must contain the complete source code, README, requirements/dependency file, configuration example where needed, and the files required to review the project.
- **Project ZIP - Google Drive Link:** Compress the final project folder into a ZIP file, upload it to Google Drive, enable reviewer access, and submit the shareable Drive link.
- **Demonstration Video - Google Drive Link:** Record a short walkthrough of the finished project, upload the video to Google Drive, enable reviewer access, and submit the shareable Drive link. The walkthrough should show the main workflow and the important results rather than only showing source files.
- **Project Documentation:** Keep the main documentation inside the repository and ZIP. The README should be complete enough for a reviewer to understand the project, set it up, run it, and verify the main results.

Submit the links in this format:

GitHub Repository	<paste repository link>
Project ZIP (Google Drive)	<paste Drive link to ZIP>
Demonstration Video (Google Drive)	<paste Drive link to video>
Documentation	README.md inside the repository and ZIP
